

Crustacean diseases of concern in Africa: White Spot Disease as a case study for exotic pathogens, & important endemic pathogens described in the region

OIE Regional Training Seminar : OIE Focal points on aquatic animals

**June 15 - 19, 2010 :
Swakopmund (NA)**

Marc Le Groumellec, Aqualma, Madagascar

Southern Africa Shrimp Farm Model: a brief presentation

- ❑ Farm Siting: Salt flat only, with minimum mangrove clearing
- ❑ Farm design: semi-intensive, big farms (up to 800 Ha); big ponds (10 Ha); Latin american model
- ❑ Water use: separation of intake and discharge. Continuous water exchange
- ❑ Feed management: high quality feed, overall good SR, growth and low FCR
- ❑ Aiming at big sizes, premium quality shrimp recognized by certifications (Label Rouge, ISO 9001, IFS/BRC, WWF private partnership)

❑ Due to bad logistics, high energy costs, the breakeven is high and is only achieved through high performances of the farm and global organization.

Southern Africa Shrimp Farm Model: a brief presentation

- ❑ Environmental responsibility: ecological surveillance of the bay, mangrove plantation programs
- ❑ Social Responsibility: building hospitals, schools, electric power, water availability.
- ❑ Health management: strict filtration, surveillance program, laboratory, pond disinfection
- ❑ Food safety: internal food safety

Conclusion: since 1991, the project respected recommendations published by FAO in its "international principles for responsible shrimp farming", aiming a long term sustainable business.

A fully integrated model

- ❑ Domestication, broodstock selection and nauplii production on the site of Moramba
- ❑ Post-larvae production on the sites of Nosy Be and Mifoko
- ❑ Shrimp grow-out ponds on Mahajamba & Besalampy
- ❑ Processing plants in Besakoa & Besalampy
- ❑ Exportation from Majunga harbour
- ❑ Cooking plant in France

Feed plant in La Reunion island

Label Rouge: certification de la qualité supérieure du produit fini

- ❑ Objectifs: Mettre en évidence la qualité du produit fini.
- ❑ Besoins : Définir the caractéristiques et souhaité communiquer car c'est du milieu de gamme. Standards originellement validés par des scientifiques. Traçabilité complète, et semestrielle!
- ❑ Bénéfices attendus : différenciation positive du produit et du marché, en produisant constamment du produit de qualité supérieure.

**Thank you
for your
attention!**

Examples of potential vectors /hosts

Big diversity of vectors, sometimes morphologically similar, but carrying different pathogens

These farms are highly submitted to a diversity of wild crustaceans, all of which are potential vectors for diseases

Disease diagnosis lab for shrimp & others

- Histopathology
- In Situ Hybridization
- Molecular Biology:
 - PCR
 - RT-PCR
- ISO Certified

Working with reference labs:

- UAZ TAA, since 1997
- Dr Lo, Taiwan
- French Universities

Updated on OIE listed and other exotic diseases
Research on new / emerging

Why other countries drastically changed their rearing methods ?

White Spot Disease case study: example of an exotic disease

White Spot Syndrome Virus* Family *Nimaviridae* n.f.; Genus *Whispovirus*; Type Species: *WSSV*

Replication	Nuclear
Morphology	enveloped, elliptical rod with prominent apical "tail"
Size	virion: 80-120 x 250-380 nm nucleocapsid: 58-67x230-350 nm
Density	1.18-1.25 g/ml
Nuclei Acid	dsDNA, circular, supercoiled, ~305 kb
ORFs	~531 ORFs for 181 functional proteins

* Various publications 1995-2002

White Spot/Red Disease Clinical Signs

- Sudden reduction in feeding, lethargic.
- Red discoloration in *P. monodon*, *L. vannamei*, *L. stylirostris*.
- Soft, loose shells
- White spots 0.5 to 2 mm under cuticle (less common in Western Hemisphere penaeids)
- Up to 100% mortality within 3 days of onset of disease signs.

Molecular of WSD

CHAPTER 2.2.3. WHITE SPOT DISEASE

1. Scope
The purpose of this chapter, white spot disease (WSD) is considered to be infection with white spot syndrome virus (WSSV).

2. Disease information

2.1. Agent factors
White spot syndrome virus (WSSV) has been identified consistently in diseased farmed freshwater fish as the aetiological agent of a newly recognized fish disease concept which is subject to change after emerging evidence indicates have been reported from other species.

2.1.1. Antigenic spot, spot virus
WSSV was assigned to the International Committee on Taxonomy of Viruses (ICTV) as the only member of the genus *Whispovirus* within the *Nimaviridae* family. Virus of WSSV are only so far reported in freshwater farmed aquatic vertebrates and members of the order in farmed and wild fish and shellfish. This virus is a double-stranded, linear, non-segmented, dsDNA virus. The virus, though having various geographical isolates with distinctive variability from near relatives, they are all considered as a single species which was provisionally named the genus *Whispovirus* (WV).

2.1.2. Survival outside the host
The agent is stable for at least 10 hours at 50°C in seawater under laboratory conditions (17) and is stable in ponds for at least 3-4 weeks (18).

2.1.3. Stability of the agent infective inoculative material
The agent is maintained in UVB irradiation at 50°C and in seawater at 50°C (18).

2.1.4. Life cycle
In vitro studies with primary cell culture and in vivo studies with pondwater (PL) show that the replication cycle is approximately 20 hours at 25°C.

2.2. Host factors
WSSV has an extremely wide host range. The virus can infect a wide range of aquatic environments including marine, brackish and freshwater penaeids, teleosts and elasmobranchs (19).

2.2.1. Susceptible host species
All cultured species (aquaculture production) from marine and brackish or freshwater systems are susceptible to WSD (6, 7, 8, 19).

2.2.2. Susceptible stages of the host
All life stages are potentially susceptible, from eggs to broodstock (8, 20).

2.2.3. Species or subpopulation production probability of detection
There is a higher probability of detecting the virus in older fish or young. The host life stages of susceptibility for infection are: egg (1), larvae (2), juveniles and adults. Probability of detection can be compared to species to provide comparative risk and host selection depending on species, changes in density, production rate and curing period (21).

2.2.4. Agent origins and related issues
The major origins of WSSV infection are from contaminated and recreational waterways origin, possibly the cultured aquaculture and introduction between species (7, 22) although WSSV which

VPL-6/4/2007 - Whispovirus

FAMILY NIMAVIRIDAE

TAXONOMIC STRUCTURE OF THE FAMILY

Family: *Nimaviridae*

Genus: *Whispovirus*

Since only one genus is currently recognized, the family description corresponds to the genus description.

GENES WHISPOVIRUS

Type Species: White spot syndrome virus

VISION PROPERTIES

MORPHOLOGY

Figure 1: (Left) Morphology of virions of white spot syndrome virus (WSSV). (Left) Schematic illustration of the structure of a typical whispovirus virion. (Top center and right) Negatively stained electron micrographs of WSSV virions (viruses, courtesy of M. Sakai and E. Hoshino) and nucleocapsids (right, courtesy of C. Lo-Ligeti) from hemolymph of infected *Penaeus monodon* shrimp. The black apparent tail was detected after thin section of WSSV-infected shrimp.

From: Lo, C.F., Aoki, T., Bonami, J.R., Fiegel, T., Lightner, D.V., Walker, F.J., and Vlak, J.M., "in press." Family Nimaviridae, Genus Whispovirus. *8th Report of the ICTV Virus Taxonomy*.

White Spot Syndrome Virus

Family *Nimaviridae*

- **WSSV causes significant disease in:**
 - All penaeids – acute disease & high mortalities
 - Crabs - several genera
 - Freshwater prawns
 - Spiny lobsters
 - Freshwater crayfish
- **Known natural & experimental hosts is > 50 species.**

White Spot Syndrome Virus

Partial List of Natural & Experimental Hosts (Western Hemisphere*)

---	--

Origin of WSSV in Asia : A European crustacean ?

Frequent cultures of mixed species in Asia, risky business

A lesson to be taken for younger aquacultures

White Spot/Red Disease

Epidemiological gross data

- **Transmission modes :**
 - Horizontal : through **cannibalism, predation on contaminated wild fauna**. **Free form** in water. Remains infectious in the soil for several days. **Birds** are an **important vector** for long distances infections of a **new zone**
 - Vertical : a female at low grade infection can produce **carriers in offsprings**.
- Temperature drops triggers the disease (below 30°C-28°C).
- Diffusion of the disease worldwide due to unregulated live and frozen animals transports

White Spot/Red Disease

Disease management

In a country free from the WS disease:

- Active and passive **surveillance**
- Regulations **forbidding imports**
- If not possible: **quarantine**
- If there is an **outbreak: early detection. Eradication.**

Fallowing is the only solution. Continued surveillance.

In a country where WSD is endemic:

- Deeply modifies the rearing methods: **water treatment is mandatory (filtration, disinfectants, pesticides ?)**, and consequently **intensification** plus **strong aeration** to reduce water exchange. Stock **SPF** post-larvae.
- National Focal Points: **zoning** or **compartmentalization ?**

White Spot Syndrome Virus (WSSV)

From Dr. P. Walker, CSIRO, Australia

The Asian pandemic

From Dr. P. Walker, CSIRO, Australia

32

THE SPREAD OF WHITE SPOT VIRUS (Year of First Occurrence by Location)

Introduction from Asia & Spread of WSSV in the Americas

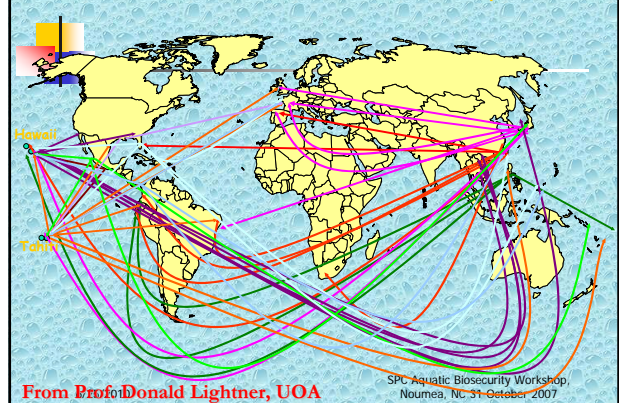

(date) = eradicated from affected farms

Penaeus monodon in Southern Africa: one of the only important regions remaining with a free status for the more nasty epidemic diseases

Global Transfers of Live Shrimp

From Prof. Donald Lightner, UOA

SPC Aquatic Biosecurity Workshop, Noumea, NC 31-October 2007

Recent movements of *Penaeus monodon* in the world

Why did Asia and Americas fail to stop this epizootics ?

Not enough knowledge on diseases shared by all stakeholders
 Low involvement of the private sector
 Nice regulations and technical guides, but smuggling and illegal imports almost everywhere

What could we learn from history ?

Capacity building of National Focal Points, including emerging diseases & early detection
 Biosecurity implementation
 Active surveillance programs (and passive through farmers)
 Capacity building of all stakeholders, network including farmers
 One good example for Africa: Australia
 We will succeed or fail together, arrival of WSD means the end of this original model, and probably the collapse of this industry
 Consider working regionally for more efficiency

→ YES WE CAN !

CCI: Central role and responsibility of OIE National Focal Points

Current regulations and strategy in Madagascar

Active regulations forbidding live or frozen crustacean imports (Décret n°2001/030)

Self declaration of freedom process, active surveillance program for WSD, TSD, YHD. Surveillance plan (active and passive) validated by an international epidemiologist expert.

Opportunity for Africa to stop exotic crustacean diseases

Opportunity to build a different approach, taking advantage of the recent development of crustacean aquaculture in Africa (not only shrimp, but crabs, lobsters, etc.). Learn for others' mistakes.

Regional organization similar to NACA required (Sarnissa, others ?)

Help from FAO, OIE needed

Share analytical and expertise resources for the region ?

CCI: crustaceans having nearly no defenses against these pathogens, the best solution is maximum prevention

Others aspects on National Focal points activities

Rickettsia Like bacteria and microsporidia case studies: examples of local disease of concern (both on Madagascar and mainland Africa)

Rickettsia Like Bacteria systemic

- Morphology: bacillary form, Gram negative.
- Dimensions: 0.45 µm x 1.5 µm.
- Replication: Cytoplasmic; not intravacuoles.
- Target tissues: connective tissues, lymphoid organ, cuticular epithelial cells, hematopoietic cells & hemocytes.
- Taxonomy: Proteobacteria, probably a gamma-proteobacteria, while NHP is an alpha-proteobacteria and Rickettsiales is a separate order. No relations with human rickettsias transmitted through arthropods (Ixodes, etc.)

Rickettsia Like Bacteria "Milky" Disease Clinical Signs

- Lethargic shrimp at the edge of the pond, presence of birds.
- No obvious impact on feed consumption or growth
- No discoloration in *P. monodon*. Dirty gills.
- Hepatopancreas pale. HP and lymphoid organ hypertrophied
- Hemolymph is white, looking like milk. Absence of clotting

PCR reaction for *Rickettsia Like Bacteria*

Madagascar Rickettsia

DNA Templates

1. Extracted frozen tissue
2. Extracted fixed tissue
3. Extracted hemolymph

PCR Reaction Mixture

Reagent	25 µl PCR Beads	Final Concentration
dH ₂ O	23.5 µl	dNTPs = 200 µM each Primers = 0.31 µM each
Ric6F	0.5 µl	MgCl ₂ = 1.5 mM Taqzyme = 2.5 U
Ric6R	0.5 µl	Duflor = 10 mM Tris, pH9, 50 mM KCl
Template	0.5 µl	

PCR Cycling Parameters

Time	Temperature (°C)	# of cycles
2 min	95	1
30 s, 2 min, 30 s	65, 72, 95	30
1 min, 2 min	45, 72	1
HOLD		4

Madagascar Rickettsia Primers

Primers	Sequence	Amplicon size
Ric6F	TGG CAG TAC GGA ATA ACC TGA G	841 bp
Ric6R	ATC TGC GCG AGA GGC ATG TCA A	

In situ hybridization with Rickettsia Like Bacteria specific probe labeled with digoxigenin

Rickettsia : natural infection of *P. monodon* by RLB. Connective tissue of hepatopancreas (intertubular)

Rickettsia: experimental infection of *L. vannamei* by RLB, lymphoid organ

NHP: natural infection of *L. vannamei* by NHP. No hybridization with RLB specific probe

Specificity of RLB ISH and generic probes (differential diagnostic)

Generic bacterial probe

RLB probe

P. monodon hepatopancreas infected by RLB (Intertubular spaces)

L. Vannamei hepatopancreas infected by NHP

RLB experimental infection: injection challenge on *Litopenaeus vannamei*

Identified and suspected vectors for RLB

Microsporidian & Haplosporidian Parasites of Penaeid Shrimp

Microsporidian	Target Tissue(s)	Spores per Sporant	Spore Dimensions
<i>Ameson</i> (= <i>Nosema</i>) <i>nelsoni</i>	Muscle	1	2.0 x 1.2 μm
<i>Ameson</i> spp.			
<i>Agmasoma</i> (= <i>Thelohania</i>) <i>penaei</i>	CT, gonads, vessels, occasionally muscle	8	8.2 x 5 μm & 5.0 x 2.0 μm
<i>Agmasoma</i> <i>duorara</i>	Muscle, CT	8	5.4 x 3.6 μm
<i>Agmasoma</i> spp.			
<i>Pleistophora</i> spp.	Muscle, heart, CT, HP	16 to 40+	2.6 x 2.1 μm
HP microsporidian of <i>Penaeus monodon</i>	HP	multiple	~2 X 1 μm
HP haplosporidian of <i>Litopenaeus vannamei</i>	HP	multiple	~2 X 2 μm* (spores not known)

Microsporidia *Ameson michaelis*

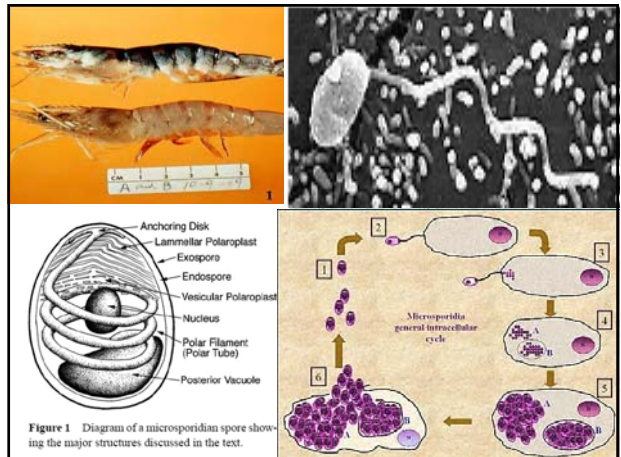

Morphology: monomorphic, ovalum spore, refringent, Gram negative, non grouped

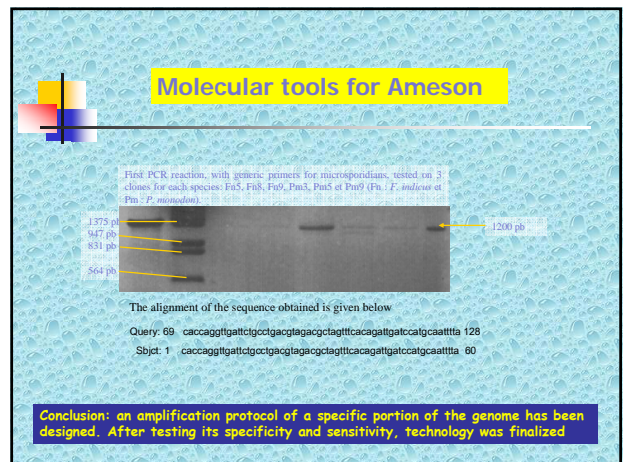

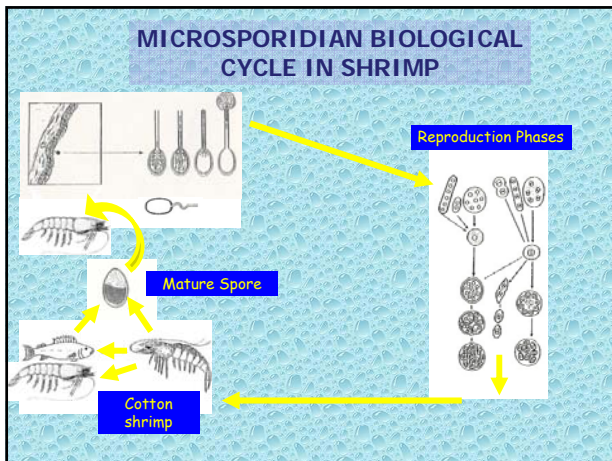

Dimensions: 0.50 μm x 1 μm

Replication: Obligatory intracellular parasite. Cytoplasmic

Target Tissue: Muscle

COTTON SHRIMP CLINICAL SIGNS

Conclusions on National focal points roles

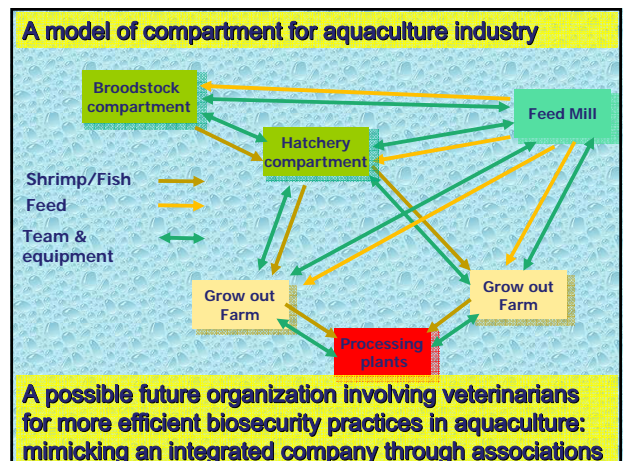

Challenges for National Focal Points:

- + Participate in **keeping Africa free** from extremely deleterious pathogens such as **WSD, YHD, TSD and IMND**
- + Deal with **emerging diseases** of the Continent
- + Design and run successfully **quarantines, zoning and compartmentalization**
- + Find ways to **involve actively private sector**, using conviction and building confidence, notably using the help of private vets or aquatic sanitary agents, as the **first front against diseases**. Reactivity is key to success. Raising biosecurity levels is necessary.

Huge responsibility for the future of crustacean aquaculture in Africa.

In parallel, domestication of local species should be actively promoted:

- + excellent exercise to quickly **learn how to close the biological cycle**, control all risks linked to aquaculture activities (**pathologic, genetic, environmental, animal welfare**).
- + **It avoids the need of live animals importations.**

The ultimate weapon for National Focal Points
to fight against both exotic and local diseases

DOMESTICATION !
